

ABSTRACT OF THE DISCLOSURE

Access to a communications network is provided to a user supporting a mobile unit capable of wireless communication with at least one access node of a local area network that is capable of connecting to the communications network. Initially, wireless communication is established between the mobile unit and the access node by associating the mobile unit with the access node. The user of the mobile unit is authenticated to enable access to the communications network. Communication with a destination on the communications network is then established, and at least some session particulars are recorded of a communications session during which the mobile unit communicates with the destination on a server on the network.
